Water Supply Outlook For Nevada

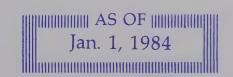

SOIL CONSERVATION SERVICE U.S. DEPARTMENT OF AGRICULTURE

Cooperating with

NEVADA DEPARTMENT OF CONSERVATION AND NATURAL RESOURCES

TO RECIPIENTS OF WATER SUPPLY OUTLOOK REPORTS:

Most of the usable water in western states originates as mountain snowfall. This snowfall accumulates during the winter and spring, several months before the snow melts and appears as streamflow. Since the runoff from precipitation as snow is delayed, estimates of snowmelt runoff can be made well in advance of its occurrence. Streamflow forecasts published in this report are based principally on measurement of the water equivalent of the mountain snowpack.

Forecasts become more accurate as more of the data affecting runoff are measured. All forecasts assume that climatic factors during the remainder of the snow accumulation and melt season will interact with a resultant average effect on runoff. Early season forecasts are therefor subject to a greater change than those made on later dates.

The snow course measurement is obtained by sampling snow depth and water equivalent at surveyed and marked locations in mountain areas. A total of about ten samples are taken at each location. The average of these are reported as snow depth and water equivalent. These measurements are repeated in the same location near the same dates each year.

Snow surveys are made monthly or semi-monthly from January 1 through June 1 in most states. There are about 1900 snow courses in Western United States and in the Columbia Basin in British Columbia. Networks of automatic snow water equivalent and related data sensing devices, along with radio telemetry are expanding and will provide a continuous record of snow water and other parameters at key locations.

Detailed data on snow course and soil moisture measurements are presented in state and local reports. Other data on reservoir storage, summaries of precipitation, current streamflow, and soil moisture conditions at valley elevations are also included. The report for Western United States presents a broad picture of water supply outlook conditions, including selected streamflow forecasts, summary of snow accumulation to date, and storage in larger reservoirs.

Snow survey and soil moisture data for the period of record are published by the Soil Conservation Service by states about every five years. Data for the current year is summarized in a West-wide basic data summary and published about October 1 of each year.

Published by Soil Conservation Service

The Soil Conservation Service publishes reports following the principal snow survey dates from January 1 through June 1 in cooperation with state water administrators, agricultural experiment stations and others. Copies of the reports for Western United States and all state reports may be obtained from Soil Conservation Service, West Technical Service Center, Room 510, 511 N.W. Broadway, Portland Oregon

Copies of state and local reports may also be obtained from the state offices of the Soil Conservation Service in the following states:

WATER SUPPLY OUTLOOK FOR NEVADA

SNOW MEASUREMENTS

A majority of the snow measurements for the January 1, 1984 Water Supply Outlook are taken from the SNOTEL system.

The snowpack in Nevada and on the eastern slope of the Sierra is again above average for the second year in a row. The January 1 snow water content is approximately 200% of average in the Tahoe Basin, 185% in the Truckee Basin, 200% in the Carson Basin, 215% in the Walker Basin, 325% in the Upper Humboldt, 320% in the Lower Humboldt, 290% in the Owyhee Basin, 235% in the Snake River Basin, and 245% in the Northern Great Basin.

The snowpack in the Tahoe, Truckee, Carson, and Walker Basins is greater than recorded last year at this time. Last year the snowpack was the largest on record and this year holds the promise of being very similar.

The Humboldt Basin snowpack is exceptional for this time of year. The Tremewan Ranch snow course recorded 5.4 inches of water content on December 29, 1983 as compared to an average of 1.0 inch and a reading of 1.9 inches last year. The Taylor Canyon snow course was read December 29, 1983 and the survey showed 10.6 inches of water as compared to an average of 2.1 inches and 5.1 reading last year.

Snowpack readings in the eastern portion of the state are also above last year's SNOTEL readings. Ward Mountain #2 is 1.2 inches above last year's value and 5.7 inches above the estimated average. Berry Creek is 3.6 inches ahead of last year and 5.8 inches above the estimated average.

The Mount Rose Ski Area water content on December 29, 1983 was 37.1 inches. The water content last year on the same date was 33.4 inches. The Echo Summit snow course water content was 27.8 inches this year and 21.3 inches last year.

The total precipitation received in the Sierra during the last two water years have been extraordinary. During the period October 1, 1981 until December 31, 1983 Ward Creek has accumulated 294.2 inches of precipitation while the Mount Rose Ski Area gage has received 229.8 inches.

RESERVOIR STORAGE

Reservoir storage on January 1 is slightly higher than last year. The combined total useable storage of seven major reservoirs is 1,211,000 acre-feet as compared to 1,070,000 acre-feet last year.

Lake Tahoe contains 652,000 acre-feet of useable storage as compared to 570,000 acre-feet last year at this time. Water is being released from Lake Tahoe to accomodate for runoff during the spring. The level of Pyramid Lake has risen 2.53 feet from October 3, 1983 to December 28, 1983. The level of Pyramid Lake is expected to continue to rise.

Storage on the Lower Colorado River is above that recorded last year. The current useable storage in Mohave is 1,658,000 acre-feet as compared to 1,646,000 acre-feet last year. Lake Mead's useable storage is 24,751,000 acre-feet compared to 23,151,000 last year, an increase of 1,600,000 acre-feet.

STREAMFLOW FORECASTS

Streamflow throughout Nevada and on the east Slope of the Sierra will continue to be well above average for the coming spring and summer. Forecasts made at this time assume average precipitation for the remainder of the season.

STREAMFLOW FORECASTS (Thousand Acre Feet) as of: January 1, 1984

Forecasts are based on snow-water presently stored in the mountain watersheds and the assumption that precipitation will be near average throughout the forecast period. Peak flow forecasts indicate the most probable range for the maximum average 24-hour flow.
